

What is claimed is:

-
1. An ellipsometer apparatus for use in providing an image of at least a portion of a sample, the ellipsometer apparatus comprising:
- 5 an objective lens having a focal plane at which a sample plane of the sample is positioned;
- an illumination source for providing incident light normal to the sample plane, wherein the incident light comprises linearly polarized light incident on the objective lens, wherein the objective lens focuses the incident linearly polarized
- 10 light onto the sample, and further wherein at least a portion of the focused incident polarized light is reflected by the sample resulting in reflected light;
- a spatial filter to modify at least a portion of the incident light or the reflected light; and
- an analyzer portion operable to generate polarization information based on
- 15 the reflected light.
-
2. The apparatus of claim 1, wherein the illumination source comprises a fiber illuminator.
- 20 3. The apparatus of claim 1, wherein the objective lens is a high numerical aperture objective lens having a numerical aperture in the range of 0.5 to less than 1.
-
- 25 4. The apparatus of claim 1, wherein the spatial filter is positioned adjacent the objective lens in an actual plane of an exit pupil thereof.
-
- 30 5. The apparatus of claim 1, wherein the spatial filter is part of the illumination source and is positioned in a conjugate plane of an exit pupil of the objective lens.

S*

6. The apparatus of claim 1, wherein the spatial filter is part of the analyzer portion and is positioned in a conjugate plane of an exit pupil of the objective lens.

7. The apparatus of claim 1, wherein the analyzer portion comprises:
5 a rotatable quarter wave plate;
an analyzer;
a lens; and
a detector, wherein the rotatable quarter wave plate, the analyzer, and the lens are positioned such that the reflected light passes through the rotatable quarter
10 wave plate and the analyzer, and further wherein the reflected light is focused onto the detector by the lens.

8. The apparatus of claim 7, wherein the detector is a charge coupled device array detector.

15

9. The apparatus of claim 1, wherein the apparatus further comprises a beam splitter for passing the linearly polarized light normal to the sample plane and incident on the objective lens, and further wherein the beam splitter diverts the reflected light to the analyzer portion.

20

10. The apparatus of claim 1, wherein the illumination source comprises a polarization converter providing for linearly polarized light with polarization states that are at +/- 45 degrees with respect to an incident plane of the linearly polarized light, and wherein the analyzer portion comprises a polarization device matched to the polarization converter of the illumination source.

25
11. The apparatus of claim 1, wherein the spatial filter is configured such that the polarization state of the light that is modified thereby is aligned at 45 degrees with respect to an incident plane of the linearly polarized light.

12. The apparatus of claim 1, wherein the illumination source includes a thin filament bulb and a low numerical aperture lens for use in projecting an image of the filament onto the sample and is operable to sweep the image across the sample.

5

13. An ellipsometry method for use in providing an image of at least a portion of a sample, the method comprising:

providing an objective lens having a focal plane at which a sample plane of the sample is positioned;

10 providing linearly polarized light normal to the sample plane incident on the objective lens;

focusing the incident linearly polarized light onto the sample, wherein at least a portion of the focused incident polarized light is reflected by the sample resulting in reflected light;

15 spatial filtering at least a portion of the incident light or the reflected light;

and

generating polarization information based on the reflected light.

14. The method of claim 13, wherein providing linearly polarized light normal to 20 the sample plane incident on the objective lens comprises:

providing light from an extended source;

collimating the light; and

linearly polarizing the collimated light.

25 15. The method of claim 13, wherein the objective lens is a high numerical aperture objective lens having a numerical aperture in the range of 0.5 to less than 1.

sel
84

16. The method of claim 13, wherein spatial filtering at least a portion of the incident light or the reflected light comprises using a spatial filter at a plane of an exit pupil of the objective lens.

5 17. The method of claim 13, wherein spatial filtering at least a portion of the incident light or the reflected light comprises using a spatial filter at a conjugate plane of an exit pupil of the objective lens.

18. The method of claim 13, wherein generating polarization information based
10 on the reflected light comprises:

passing the reflected light through an analyzer portion comprising at least a rotatable quarter wave plate and an analyzer;

rotating at least the rotatable quarter wave plate to at least two angular positions;

15 detecting at least two polarization images corresponding to the at least two angular positions.

19. The method of claim 18, wherein generating polarization information based on the reflected light further comprises generating an image using at least one of a ratio and a difference of the at least two polarization images.

20. The method of claim 18, wherein the method further comprises:

rotating the analyzer of the analyzer portion to one or more positions; and generating additional polarization images corresponding to the one or more

25 positions.

21. The method of claim 13, wherein providing linearly polarized light normal to the sample plane incident on the objective lens comprises providing linearly polarized light with polarization states that are at +/- 45 degrees with respect to an

000000000000000000000000

incident plane of the linearly polarized light using a polarization converter, and further wherein generating polarization information based on the reflected light comprises generating polarization information based on the reflected light using a polarization device matched to the polarization converter.

5

22. The method of claim 13, wherein spatial filtering at least a portion of the incident light or the reflected light comprises providing a spatial filter configured such that the polarization state of the light that is modified thereby is aligned at 45 degrees with respect to an incident plane of the linearly polarized light incident on
10 the objective lens.

23. The method of claim 22, wherein generating polarization information based on the reflected light comprises:

15 passing the reflected light through an analyzer portion comprising at least a rotatable quarter wave plate and an analyzer; and

synchronously rotating the rotatable quarter wave plate, the analyzer, and the spatial filter to obtain a plurality of polarization images.

24. The method of claim 13, wherein providing linearly polarized light normal to
20 the sample plane incident on the objective lens comprises providing light such that an illumination line is focused on the sample, and further wherein the method comprises sweeping the illumination line across the sample.
